

# MSE for the southern bluefin tuna (SBT)

## SBT reported catch by flag (in 1000 tonnes)

Heavily fished in the past, with the annual catch reaching 80,000 t in the early 1960s, now down to about 12,000 t.

# SBT stock status

# In 2001 CCSBT approved a multi-year plan for the Scientific Committee to design a rebuilding plan for SBT

Member country and external scientists designed simulation-testing protocols

Proposed and evaluated different candidate management procedures (strategies)

# CCSBT convention objective

---

To ensure, through appropriate management, the conservation and optimum utilisation of southern bluefin tuna

## Background

“Classical” stock assessment -> TAC approach **failed**

- Restructured scientific advisory process (2000)
  - Independent chairs for SC
  - Independent advisory panel

### Task:

- Develop Management Procedure  
i.e., a **harvest control rule (HCR)**

# The task

---

- Define “**operating models**”
  - Incorporate uncertainty about the stock, dynamics and sampling
- Use to test candidate HCR
  - Proposed by member scientists

Find HCR that is robust to uncertainties, achieves rebuilding objectives and maintains a viable industry

# The approach

---

- Annual workshops (4) with very clear terms of references and benchmarks
- All scientists used same code and agreed protocols for testing procedures
- Iterative consultative process
  - Informed stakeholders and
  - Got feedback about alternatives and priorities between conflicting objectives
- Candidate HCRs evaluated by agreed performance statistics

# Step 1- Choice of operating models

---

## Key axes of uncertainty

- Level of productivity (*steepness of SR*)
- Level of natural mortality
- Interpretation of CPUE

Currently an ensemble of 320 “models”

## Translating convention objective to HCR Testing

---

- Managers define explicit goals/objectives
- Scientific Committee tasked to design a strategy (MP) to meet those goals/objectives

# What managers and industry wanted

---

- Rebuild the stock to 1980 levels by 2020
- Reduce short-term risks to the stock
- Hold catches at current levels or higher if the stock increases
- Reduce year-to-year variability in catches

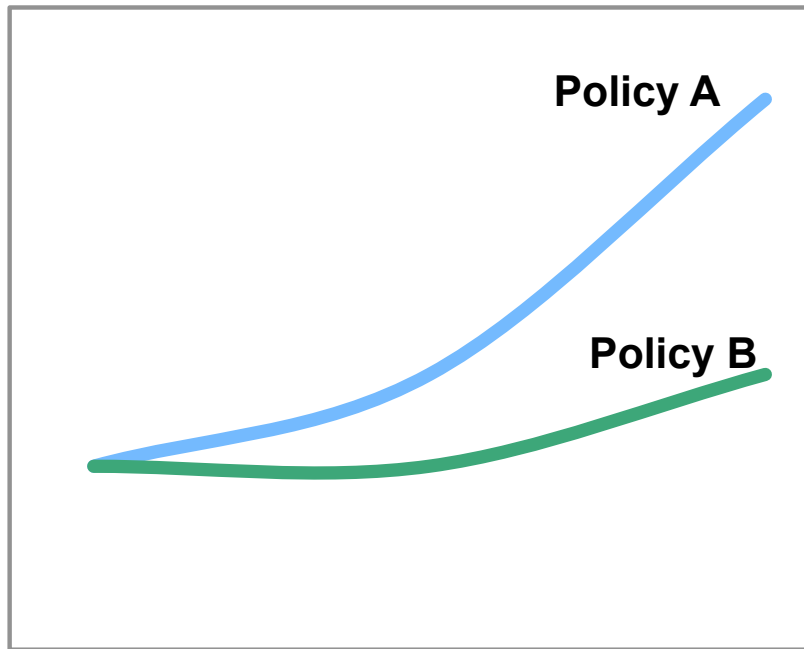

**Evaluating trade-offs needed for  
informed decisions**

# Primary trade-off

Between rebuilding rate and average catch

Spawning biomass

Catch

2002

2008

2014

2020

2002

2008

2014

2020

# Secondary trade-off

Candidate HCR “tuning”

Achieve same rebuilding (in median terms)

trade-offs between short-term catch stability and risks examined

Spawning biomass

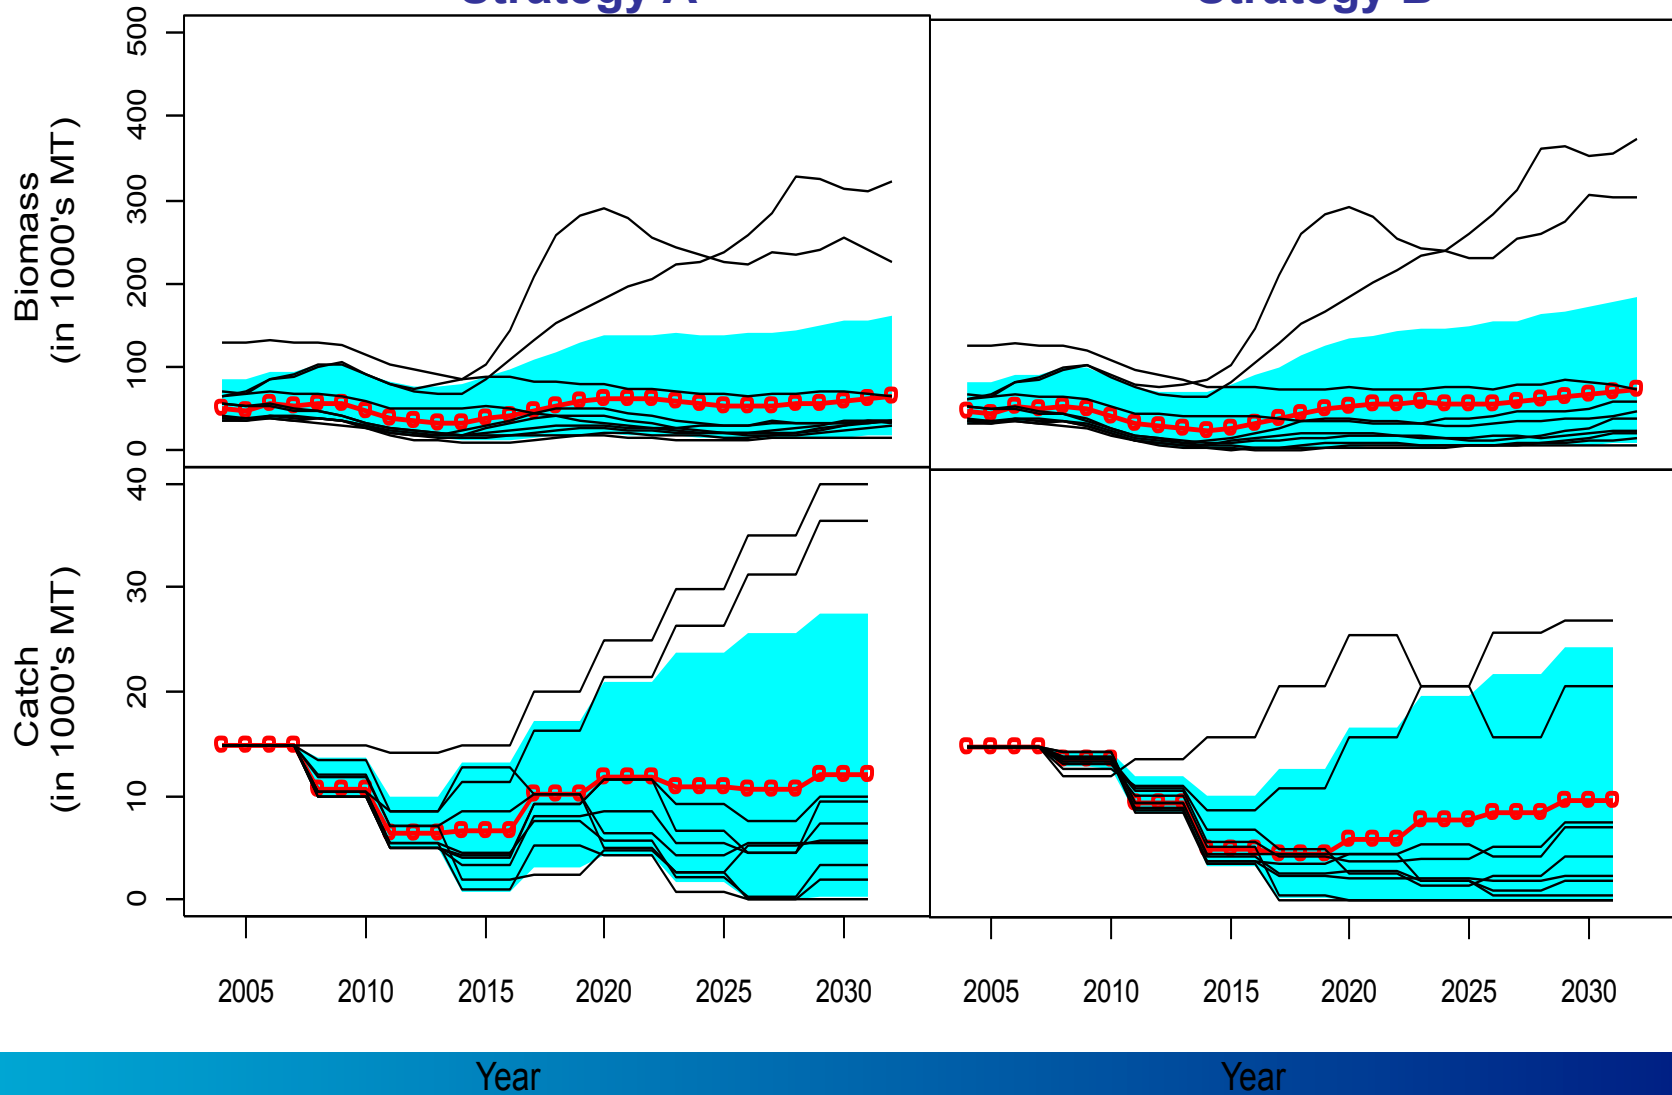

Catch

### Strategy A

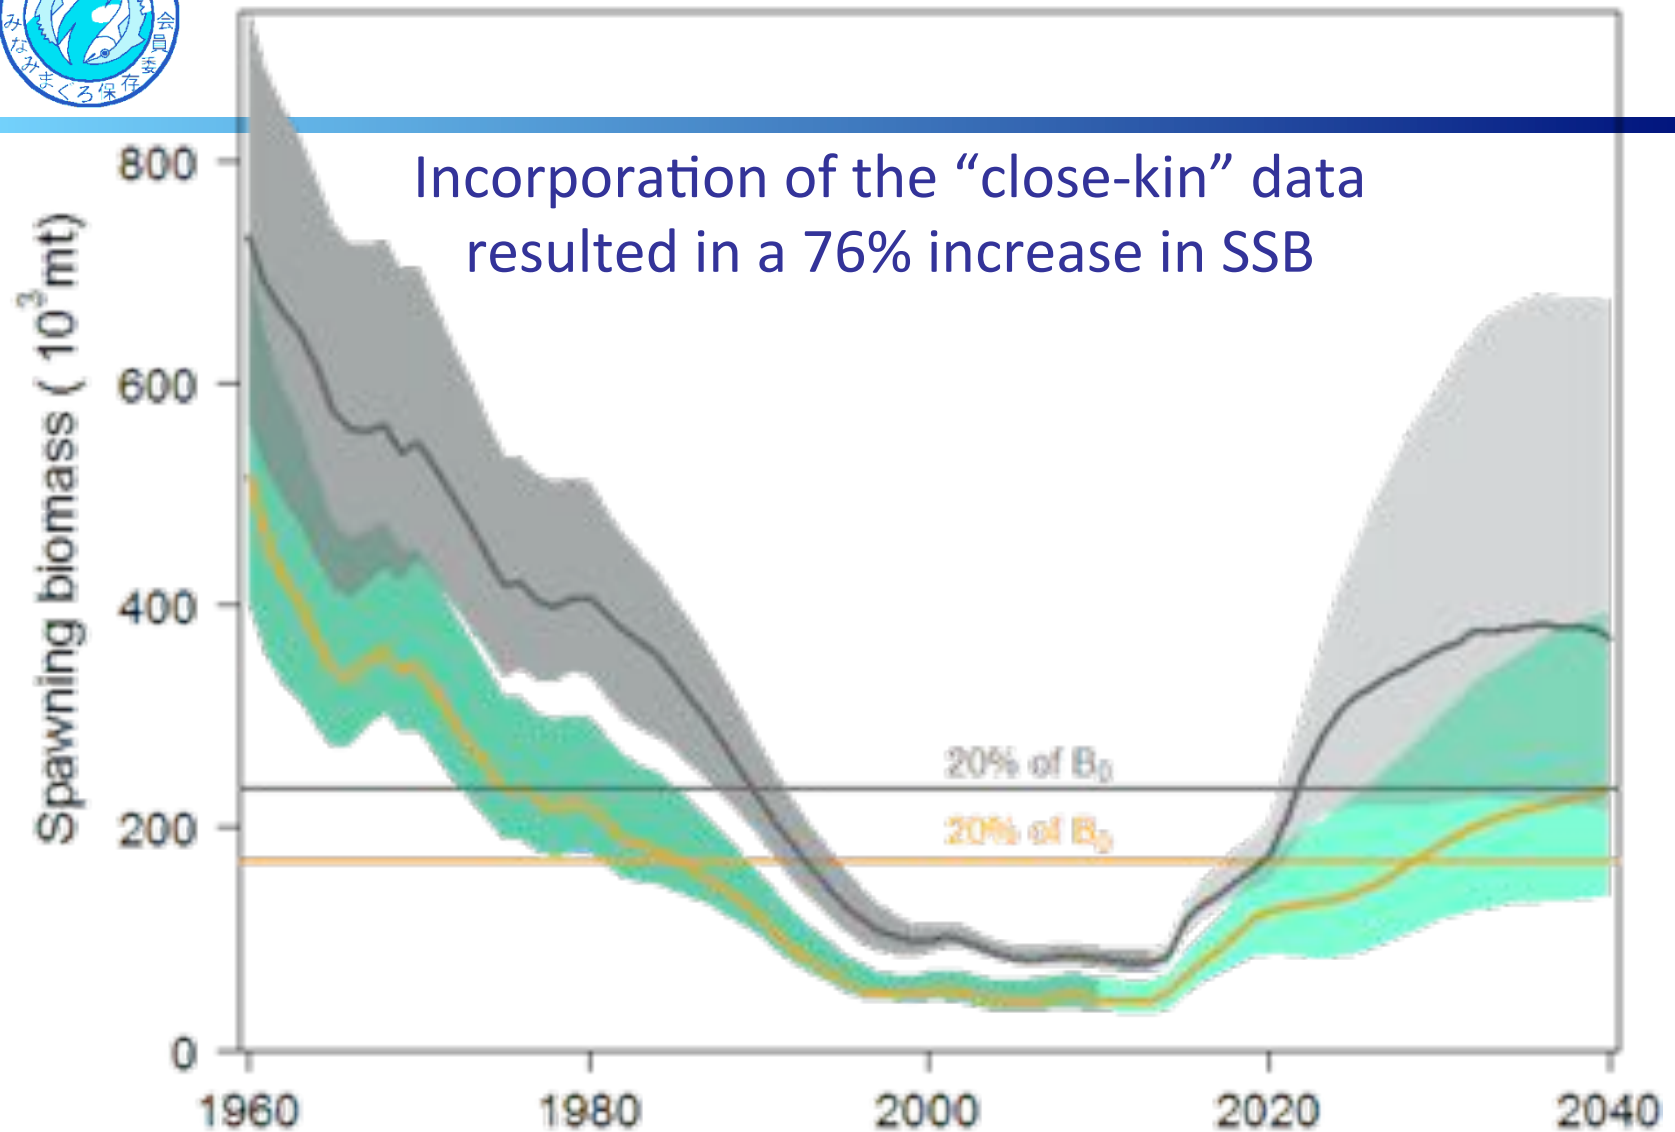

### Strategy B

Incorporation of the “close-kin” data  
resulted in a 76% increase in SSB

A major change in the stock assessment did not lead to a change in the recommended MP

# Summary of CCSBT MSE

- Changed focus of scientific process from endless debates on abundance estimates and TACs to discussion of the testing protocols used for developing effective decision rules
- Testing of alternative decision rules transparent to all members
- Valuable exchanges between industry, managers and scientists

***Communication key***
